## 1. Problem formulation

image $\boldsymbol{u}$ is stored in a vector in $\mathbb{R}^{p} \quad$ data $\boldsymbol{v} \in \mathbb{R}^{q}$

$$
\begin{aligned}
\mathcal{F}(u) & =\|A u-v\|_{1}+\beta \sum_{j \in J} \varphi\left(\left\|\mathrm{G}_{j} u\right\|_{2}\right) \\
& =\sum_{i \in I}\left|a_{i} u-v[i]\right|+\beta \sum_{j \in J} \varphi\left(\left\|\mathrm{G}_{j} u\right\|_{2}\right), \quad \beta>0 \\
I & \stackrel{\text { def }}{=}\{1, \cdots, q\} \\
J & \stackrel{\text { def }}{=}\{1, \cdots, r\} .
\end{aligned}
$$

where

- $A$ is a matrix of any rank with rows $a_{i} \in \mathbb{R}^{1 \times p}$
- $\mathrm{G}_{j}$ are matrices or vectors (e.g. discrete gradient operators)
- $\varphi$ is concave on $\mathbb{R}_{+}$

This family of objective functions has never been considered before

|  | (f1) | (f2) | (f3) | (f4) |
| :---: | :---: | :---: | :---: | :---: |
| $\varphi(t)$ | $\frac{\alpha t}{\alpha t+1}$ | $1-\alpha^{t}$ | $\ln (\alpha t+1)$ | $(t+\varepsilon)^{\alpha}$ |
|  | $\alpha>0$ | $0<\alpha<1$ | $\alpha>0$ | $0<\alpha<1, \varepsilon>0$ |

Functions $\varphi: \mathbb{R}_{+} \rightarrow \mathbb{R}_{+}$

Plots of the PFs $\varphi$. Note that (f1) an (f2) are bounded above, (f3) and (f4) are coercive.

## Motivation

$\hat{u}$-(local) minimizer of $\mathcal{F}$

- nonsmooth regularization $\sum_{j \in J} \varphi\left(\left\|\mathrm{G}_{j} u\right\|_{2}\right)$ with $\varphi^{\prime}(0)>0$ (e.g. TV)
$\Rightarrow \quad$ many $j$ such that $\mathrm{G}_{j} \hat{u}=0 \quad$ [Nikolova 2000, 2004]
- $\ell_{1}$ data fidelity $\|A u-v\|_{1}=\sum_{i \in I}\left|a_{i} u-v[i]\right|$

$$
\Rightarrow \quad \text { many } i \text { such that } a_{i} \hat{u}=v[i]
$$

[Nikolova 2002, 2004]

- our $\mathcal{F}$ can be seen as an extension of L1-TV
[Chan, Esedoglu 2005]
[Chan, Esedoglu, Nikolova 2006]

2. Peculiar Properties of Minimizers

Illustrations by minimizing $\mathcal{F}(u)=\|u-v\|_{1}+\beta \sum_{i=1}^{p-1} \varphi(|u[i+1]-u[i]|)$

$$
\beta \in\{157, \cdots, 400\}
$$

Data samples ( $\circ \circ \circ$ ), Minimizer samples $\hat{u}[i](+++)$.

Data samples (○○○) are corrupted with Gaussian noise. Denoising. Minimizer samples $\hat{u}[i]$ $(+++)$. Original $(---) . \beta$-the largest value so that the gate at 71 remains.

Constant pieces—solid black line.
Data points $v[i]$ fitted exactly by the minimizer $\hat{u}(\diamond)$.

Numerical evidence:
critical values $\beta_{1}, \cdots, \beta_{n}$ such that

- $\beta \in\left[\beta_{i}, \beta_{i+1}\right) \Rightarrow$ the minimizer remains unchanged
- $\beta \geqslant \beta_{i+1} \quad \Rightarrow$ the minimizer is simplified

Main assumptions

$$
\mathrm{G}=\left[\mathrm{G}_{1}^{T}, \cdots, \mathrm{G}_{r}^{T}\right]^{T}
$$

H1 $\operatorname{ker} A \cap \operatorname{ker} G=\{0\}$.
$\mathbf{H} 2 \varphi: \mathbb{R}_{+} \rightarrow \mathbb{R}$ in $\mathcal{F}$ obeys:

- $\varphi: \mathbb{R}_{+} \rightarrow \mathbb{R}_{+}$is $\mathcal{C}^{2}$ on $\mathbb{R}_{+}^{*} \stackrel{\text { def }}{=} \mathbb{R}_{+} \backslash\{0\}$ and $\varphi(t)>\varphi(0), \quad \forall t>0$;
- $\varphi^{\prime}\left(0^{+}\right)>0$ and $\varphi^{\prime}(t)>0$ on $\mathbb{R}_{+}^{*}$.
- $\varphi^{\prime \prime}$ is increasing on $\mathbb{R}_{+}^{*}, \varphi^{\prime \prime}(t)<0, \forall t>0$ and
$\lim _{t \searrow 0} \varphi^{\prime \prime}(t)<0$ is well defined and finite.

## Example

Given $v \neq 0$, consider the function

$$
\mathcal{F}(u)=|u-v|+\beta \varphi(|u|) \text { for } \varphi(u)=\frac{\alpha u}{1+\alpha u}, \quad \forall u \in \mathbb{R}
$$

The necessary conditions for $\mathcal{F}$ to have a (local) minimum at $\hat{u} \neq 0$ and $\hat{u} \neq v$ fail:

$$
\hat{u} \notin\{0, v\} \Rightarrow\left\{\begin{array}{r}
D \mathcal{F}(\hat{u})=\operatorname{sign}(\hat{u}-v)+\beta \varphi^{\prime}(|\hat{u}|) \operatorname{sign}(\hat{u})=0 \\
D^{2} \mathcal{F}(\hat{u})=\beta \varphi^{\prime \prime}(|\hat{u}|)<0
\end{array}\right.
$$

$\mathcal{F}$ does have minimizers $\Rightarrow \hat{\boldsymbol{u}} \in\{0, v\}$.

## Main theoretical results

- $\left\{\hat{u} \in \mathbb{R}^{p} \mid \mathcal{F}(\hat{u})=\inf _{u \in \mathbb{R}^{p}} \mathcal{F}(u)\right\} \neq \varnothing$
- All (local) minimizers of $\mathcal{F}$ are strict
- Let $\hat{\boldsymbol{u}} \in \mathbb{R}^{p}$ be a (local) minimizer of $\mathcal{F}$. Set

$$
\begin{aligned}
& \widehat{I}_{0}=\left\{i \in I: a_{i} \hat{u}=v[i]\right\} \\
& \widehat{J}_{0}=\left\{j \in J: \mathrm{G}_{j} \hat{u}=0\right\}
\end{aligned}
$$

$\Rightarrow \hat{\boldsymbol{u}}$ is the unique solution of the liner system

$$
\begin{cases}a_{i} u=v[i] & \forall i \in \widehat{I}_{0} \\ G_{j} u=\mathbf{0} & \forall j \in \widehat{J}_{0}\end{cases}
$$

$\Rightarrow$
( $\star$ ) the matrix with rows $\left(a_{i}, \forall i \in \widehat{I}_{0}\right.$ and $\left.\mathrm{G}_{j}, \forall j \in \widehat{J}_{0}\right)$ has full column rank
$(\star)$ is a necessary condition for a (local) minimizer
$\Rightarrow \quad$ "contrast invariance" of (local) minimizers since $\hat{u}$ is linear in $v$

## Example

The data vector $v$ is of length $\mathbf{8 0}$.
One checks that the minimizer meets

$$
\widehat{I}_{0}^{c}=(28,29,30,31,69,70) \quad \text { and } \quad \widehat{J}_{0}^{c}=(4,20,44,59)
$$

The matrix with rows $\left(a_{i}, \forall i \in \widehat{I}_{0}\right.$ and $\left.\mathrm{G}_{j}, \forall j \in \widehat{J}_{0}\right)$ is of size $149 \times 80$.
Its rank is $\mathbf{8 0}$.

- Let $\hat{u} \in \mathbb{R}^{p}$ be a (local) minimizer of $\mathcal{F}$. Then

$$
1 \leqslant k \leqslant p \Rightarrow \begin{cases}\exists i \text { obeying } a_{i} \hat{u}=v[i] & \text { such that } a_{i}[k] \neq 0 \\ \exists j \text { obeying } \mathrm{G}_{j} \hat{u}=0 & \text { or } \\ \text { such that } \mathrm{G}_{j}(k) \neq 0\end{cases}
$$

where $\mathrm{G}_{j}(k)$ is the $k$-th column of the linear operator $\mathrm{G}_{j}$

- $\Rightarrow$ each pixel of a (local) minimizer $\hat{u}$ of $\mathcal{F}$ is involved in (at least) one data equation that is fitted exactly $a_{i} \hat{u}=v[i]$, or in (at least) one vanishing operator $\left\|\mathrm{G}_{j} \hat{u}\right\|_{2}=0$, or in both types of equations.
- If $A=\mathrm{Id}$ and $\mathrm{G}_{j}$ yield discrete gradients or first-order finite differences between adjacent samples, a (local) minimizer is composed partly of constant patches, partly of pixels that fit data samples exactly, remind the figure.

## 3. Numerical scheme

Continuation approach

$$
\begin{aligned}
& \varphi_{\varepsilon}, \varepsilon \in[0,1] \text { where } \varphi_{0}(t)=t \text { and } \varphi_{1}=\varphi \\
& \varphi_{\varepsilon}(t)=\psi_{\varepsilon}(t)+\alpha_{\varepsilon} t \quad \text { where } \quad \alpha_{\varepsilon}=\varphi_{\varepsilon}^{\prime}\left(0^{+}\right)
\end{aligned}
$$

$\varphi_{\varepsilon}$ for $\varepsilon \in(0,1]$ satisfies H 2 .

$$
\begin{aligned}
\mathcal{F}_{\varepsilon}(u) & =\|A u-v\|_{1}+\beta \alpha_{\varepsilon} \sum_{j \in J}\left\|\mathrm{G}_{j} u\right\|_{2}+\beta \Psi_{\varepsilon}(u) \\
\text { where } \quad \Psi_{\varepsilon}(u) & =\sum_{j \in J} \psi_{\varepsilon}\left(\left\|\mathrm{G}_{j} u\right\|_{2}\right)
\end{aligned}
$$

For each $\varepsilon$ fixed—variable splitting and penalty decomposition techniques:
$\mathcal{J}_{\varepsilon, \gamma}(u, w, z)=\gamma\|A u-w\|_{2}^{2}+\|w-v\|_{1}+\beta \Psi_{\varepsilon}(u)+\gamma\|\mathrm{G} u-z\|_{2}^{2}+\beta \alpha_{\varepsilon} \sum_{j \in J}\left\|z_{j}\right\|_{2}$, for $\gamma \rightarrow \infty$
Alternate optimization: $\left\{\begin{array}{l}z^{(k)}=\arg \min _{z} \mathcal{J}_{\varepsilon, \gamma}\left(u^{(k-1)}, w^{(k-1)}, z^{(k-1)}\right) \\ w^{(k)}=\arg \min _{w} \mathcal{J}_{\varepsilon, \gamma}\left(u^{(k-1)}, w^{(k-1)}, z^{(k)}\right) \\ u^{(k)}=\arg \min _{u} \mathcal{J}_{\varepsilon, \gamma}\left(u, w^{(k)}, z^{(k)}\right)\end{array}\right.$
Then

$$
\begin{gathered}
z_{j}^{(k)}=\frac{\mathrm{G}_{j} u^{(k-1)}}{\left\|\mathrm{G}_{j} u^{(k-1)}\right\|_{2}} \max \left\{\left\|\mathrm{G}_{j} u^{(k-1)}\right\|_{2}-\frac{\beta \alpha_{\varepsilon}}{2 \gamma}, 0\right\}, \quad \forall j \in J . \\
w_{i}^{(k)}=\frac{A u^{(k-1)}-v}{\left\|A u^{(k-1)}-v\right\|_{2}} \max \left\{\left\|A u^{(k-1)}-v\right\|_{2}-\frac{1}{2 \gamma}, 0\right\}, \quad \forall i \in I . \\
u^{(k)} \text { solves arg } \min _{u \in \mathbb{R}^{p}}\left\{\gamma\left\|A u-w^{(k)}\right\|_{2}^{2}+\gamma\left\|\mathrm{G} u-z^{(k)}\right\|_{2}^{2}+\beta \Psi_{\varepsilon}(u)\right\}
\end{gathered}
$$

where Quasi Newton method with preconditioning is used
$\Rightarrow$ fast algorithm

## MR Image Reconstruction from Highly Undersampled Data

Reconstructed images from $7 \%$ noisy randomly selected samples in the $k$-space.

## MR Image Reconstruction from Highly Undersampled Data

Zero-filling Fourier recovery

$\|\cdot\|_{2}^{2}+\mathrm{TV}$

Our method, $\varphi(t)=\frac{\alpha t}{\alpha t+1}$

Reconstructed images from $5 \%$ noisy randomly selected samples in the $k$-space.

## Cartoon

Observed

$\ell_{1}-T V$

Our method, $\varphi(t)=\frac{\alpha t}{\alpha t+1}$

## 5. Concluding remarks

- The (local) minimizers of the proposed objectives inherit some features of $L_{1}-\mathrm{TV}$ (e.g. "scale-invariance") but in a much sharper way.
- In practice, they neatly outperform $L_{1}-\mathrm{TV}$.
- All (local) minimizers are strict.
- Bounded above functions (like f1 and f2) yield much better numerical results than coercive functions (like f3 and f4).

We do not have a theoretical explanation.

- The regularization parameter $\beta$ is not involved in the computation of a local minimizer. Implicitly, $\beta$ helps the selection of the subsets $\widehat{I}_{0}$ and $\widehat{J}_{0}$.

The ordering of the (local) minimizers $\hat{u}$ of $\mathcal{F}$ according to their value $\mathcal{F}(\hat{u})$ is determined by $\beta$.

Thank you for your attention.

## Warmest wishes to Stan!

Thanks to Raymond for the invitation.
